

KNAPSACK AUCTION

KNAPSACK PROBLEM

INPUT: $I = \{1, \dots, n\}$ items
 s_i = size for each item, $\in \mathbb{N}^+$
 w_i = value for each item, $\in \mathbb{N}^+$
 C = maximum capacity of the knapsack, $\in \mathbb{N}^+$

QUESTION: which items should be selected to maximise the value but not exceeding C ?

Formally:
$$\text{arg max}_{I \subseteq I} \sum_{i \in I'} w_i$$

$$\text{s.t. } \sum_{i \in I'} s_i \leq C$$

Algorithm

| | | | | | | | | |
|-------|-------|-------|-------|---|-----------------|-----------------|--|---|
| | 1 | 2 | 3 | 4 | 5 | 6 | | C |
| l_1 | | | w_1 | | | | | |
| l_2 | | w_2 | w_1 | | w_1, w_2 | | | |
| l_3 | w_3 | w_2 | w_1 | | w_1, w_2, w_3 | w_1, w_2, w_3 | | |
| | | | | | | | | |
| | | | | | | | | |

$w_1 = 3$
 $w_2 = 2$
 $w_3 = 1$

It is a dynamic programming algorithm: given a row, we copy it in the next one and add the item to each allocation. If there are two allocations with the same weight we keep the most valuable. At the end, we extract from the last row the allocation with the highest value.

For every item, we produce at most C elements: $O(nC)$. where is the hardness? to represent C we need m bits, it's a natural number, so $C = 2^m$ it is exponential!

⊗ (vedi dietro)

We can adopt this algorithm for auctions: $w_i = \theta_i$, the value of the bid

| | | | | | |
|-------|-------|-------|-------|-------|-------|
| s_i | 5 | 2 | 7 | 1 | 3 |
| w_i | 7 | 4 | 10 | 3 | 5 |
| | i_1 | i_2 | i_3 | i_4 | i_5 |

$C = 12$

| | | | | | | | | | | | | |
|-------|-------|-------|-------------|---|-------|-------------|-------------|-------------------|-------------------|-------------------|----|-------------|
| | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
| i_1 | | | | | w_1 | | | | | | | |
| i_2 | | w_2 | | | w_2 | | $w_2 + w_2$ | | | | | |
| i_3 | | w_2 | | | w_2 | | $w_2 + w_2$ | | $w_2 + w_3$ | | | $w_1 + w_3$ |
| i_4 | w_4 | w_2 | $w_2 + w_4$ | | w_1 | $w_2 + w_4$ | $w_1 + w_2$ | $w_1 + w_2 + w_4$ | $w_2 + w_3$ | $w_2 + w_3 + w_4$ | | $w_1 + w_3$ |
| i_5 | w_4 | w_2 | $w_2 + w_4$ | | w_1 | $w_1 + w_4$ | $w_1 + w_2$ | | $w_2 + w_4 + w_5$ | $w_2 + w_3 + w_4$ | | |
| tot | 3 | 4 | 7 | | 7 | 10 | 11 | 14 | 15 | 17 | | 17 |

$w_1 + w_4 > w_5$

C1 row error!!
 $w_1 + w_2 > w_3$

$w_2 + w_3 < w_2 + w_4 + w_5$

$w_2 + w_3 + w_4 > w_2 + w_2 + w_5$

Best allocations: i_2, i_3, i_4 ; $i_1 + i_3$ — — — — — $\rightarrow P_1 = 17 - (17 - 7) = 17 - 10 = 7$
 $\rightarrow P_3 = 17 - (17 - 10) = 17 - 7 = 10$
 $P_2 = P_4 = P_5 = 0$

- ⊛ KNAPSACK AUCTION: a knapsack auction is defined as:
 - $N = \{1, \dots, n\}$ players;
 - $I = \{1, \dots, n\}$ items;
 - $\delta = \{\delta_1, \dots, \delta_n\}, \delta_i \in \mathbb{N}^+$, size of items
 - $w = \{w_1, \dots, w_n\}, w_i \in \mathbb{N}^+$, value of item i and private info of player i .
 - C = capacity
 - $\Theta_i \subset \mathbb{N}^+$, space of types of player i , $\Theta_i = w_i$
 - $K \subseteq I$ is the set of feasible allocations s.t. $\sum_{i \in K} \delta_i \leq C$
 - $v_i(w, \Theta_i) = \begin{cases} \Theta_i, & i \in K \\ 0, & \text{otherwise} \end{cases}$

• VCG mechanism can be applied to the knapsack auction, requiring an algorithm to find the exact solution of knapsack, but no polynomial time algorithm exists for such problem unless $P = NP$.
